## Disclaimer
Acute red eye is a common presenting complaint to primary care physicians.\[1\] A detailed history of the presenting symptoms and previous ophthalmological and medical history can narrow the differential diagnosis and aid in the interpretation of key examination findings. The lack of specialist equipment in the primary care setting, along with a very broad differential diagnosis, can cause difficulty in establishing the correct diagnosis, and in such cases a specialist ophthalmological opinion should be sought.\[2\] Serious vision-threatening conditions that present as red eye are rare and can occasionally be overshadowed by associated systemic symptoms; in light of this they should always be considered within the differential and excluded on examination.\[3\]
Aetiology

The causes of acute red eye can be considered within the following categories:[4]

Adnexal causes

- Trichiasis: posterior misdirection of the eyelashes from the normal site of origin
- Entropion: inward turning of the eyelid margin
- Ectropion: outward turning of the eyelid margin
- Blepharitis: inflammation of the eyelid margin
- Dry eye: symptoms or signs consistent with a deficiency of the precorneal tear film.

Conjunctival causes

- Bacterial conjunctivitis: inflammation of the conjunctiva caused by bacterial infection
- Viral conjunctivitis: inflammation of the conjunctiva caused by viral infection
- Allergic (vernal) conjunctivitis: inflammation of the conjunctiva occurring during an allergic response
- Neonatal conjunctivitis: inflammation of the conjunctiva within the first month of life
- Subconjunctival haemorrhage
- Subtarsal foreign body
- Conjunctival foreign body.

Corneal causes

- Bacterial corneal ulcer: corneal epithelial defect caused by bacterial infection
- Viral corneal ulcer: corneal epithelial defect caused by viral infection
- Fungal corneal ulcer: corneal epithelial defect caused by fungal infection
- Contact lens-related
- Corneal foreign body
- Corneal abrasion: corneal epithelial defect usually caused by trauma.

Inflammatory causes

- Anterior uveitis: inflammation of the anterior portion of the uveal tract
Assessment of red eye

Overview

• Scleritis: inflammation of the sclera

• Episcleritis: inflammation of the episclera.

Traumatic causes

• Physical

• Chemical.

Other

• Angle-closure glaucoma: closure of the iridocorneal angle leading to an acute rise in intra-ocular pressure.

Most common conditions

Those commonly presenting to a primary care physician are:

• Infective conjunctivitis

• Allergic conjunctivitis

• Dry eye and other adnexal problems.

Sight-threatening causes

Causes of red eye that can threaten vision by leading to reduced visual acuity include:

• Angle-closure glaucoma

• Chemical injuries

• Conditions affecting the cornea

• Trauma

• Anterior uveitis.

Causes of red eye that can threaten vision by leading to globe rupture or perforation include:
Assessment of red eye

**Overview**

- Scleritis
  
  ![Fig-16](image)

- Physical trauma
- Corneal ulceration
- High-velocity foreign bodies.

These are discussed further with initial management in Emergencies: Urgent Considerations.

**Risk factors**

Risk factors associated with specific causes of red eye include:

- **Anterior uveitis:**
  
  ![Fig-15](image)

  HLA-B27 histocompatibility complex-positive patients, tuberculosis, syphilis, Lyme disease, sarcoidosis, Behcet's disease, and pauciarticular juvenile chronic arthritis.

- **Scleritis:**
  
  ![Fig-16](image)

  connective tissue disorders including rheumatoid arthritis, granulomatosis with polyangiitis (Wegener's), systemic lupus erythematosus (SLE), and relapsing polychondritis.

- **Episcleritis:**
  
  ![Fig-17](image)

  connective tissue disorders including rheumatoid arthritis, granulomatosis with polyangiitis (Wegener's), and SLE.

- **Angle-closure glaucoma:**
  
  ![Fig-19](image)

  hypermetropia, mydriatics, and systemic anticholinergic medications.

- **Subconjunctival haemorrhage:**
  
  ![Fig-9](image)

  hypertension, systemic anticoagulation, bleeding abnormalities (leukaemia, clotting disorders), conjunctival vascular lesion, trauma (including contact lens-related injury), and diabetes.

- **Dry eye:**
  
  ![Fig-5](image)

  connective tissue disorders including Sjogren's syndrome, rheumatoid arthritis, and SLE.
Urgent considerations

(See Differential diagnosis for more details)

Patients suspected of having any one of the following immediately sight-threatening conditions should be referred urgently for a same-day assessment by an ophthalmologist.

**Angle-closure glaucoma**

This is a vision-threatening condition. Symptoms suggestive of angle-closure glaucoma include:

- Pain in the affected eye
- Blurred vision
- Halos around lights seen from one eye
- Headache
- Associated nausea or vomiting.

If suspected, then immediate referral for an ophthalmological opinion and treatment should be sought. Delay in the diagnosis and referral of angle-closure glaucoma has been shown to be detrimental to the final outcome.[7]

Immediate treatment consists of carbonic anhydrase inhibitors, such as acetazolamide or methazolamide, to decrease aqueous humour formation. [Fig-19]

**Trauma: chemical injury**

Chemical injuries, especially from alkali-based solutions, are potentially extremely serious and can lead to long-term ocular surface problems. Immediate irrigation with water or 0.9% saline solution to remove the reservoir of chemicals from the eye should be attempted before any other procedures.[8] The amount of irrigation required is dependent on the pH of the tear film. After the pH has normalised, referral for further ophthalmological management is advised.[9]

**Corneal ulcer**

Bacterial, viral, or fungal corneal ulcers are vision-threatening conditions that need to be referred to an ophthalmologist to ensure appropriate treatment to limit corneal scarring. Corneal ulcer can lead to perforation of the eye. [Fig-11] [Fig-12] [Fig-18]

**Contact lens-related red eye**

This is potentially a vision-threatening condition and needs to be referred to an ophthalmologist to ensure appropriate treatment to limit corneal scarring. The patient should be advised to cease use of their contact lenses and take the contact lenses to the local eye hospital where they are seen.
Corneal foreign body

Any history of a high-velocity injury (hammer usage) should be referred for appropriate and immediate imaging, as any high-velocity foreign body may penetrate the globe. This, and non-penetrating corneal foreign bodies, are potentially vision-threatening conditions and require referral to an ophthalmologist to ensure appropriate treatment.

[Fig-13]

Penetrating ocular trauma

Very gentle initial examination is required to prevent possible expulsion of intra-ocular contents. Prompt specialist treatment is required to reduce the risk of sight- and eye-threatening complications.

Scleritis

Scleritis is potentially a vision-threatening condition. Certain forms of scleritis can lead to perforation of the globe and reduced visual acuity.[10] If global perforation is suspected, the eye should be shielded and palpation should be avoided. It should be evaluated further by an ophthalmologist. Scleritis is commonly associated with connective tissue disorders including rheumatoid arthritis, granulomatosis with polyangiitis (Wegener’s), systemic lupus erythematosus, and relapsing polychondritis.

[Fig-16]

[Fig-18]

Neonatal conjunctivitis

Neonatal conjunctivitis (ophthalmia neonatorum) is usually a mild illness. However, untreated infection (for example with gonococcus, chlamydia, pseudomonas, or herpes) can lead to sight-threatening complications and potentially serious systemic infection.[11] [12] Complications of neonatal conjunctivitis due to chlamydia include superficial corneal vascularisation, conjunctival scarring, and pneumonia. Complications due to gonorrhoeal infections include corneal scarring, ulceration, panophthalmitis, perforation of the globe, and permanent visual impairment.[11] [12] [13] Patients with suspected neonatal conjunctivitis should be referred immediately to ophthalmology.[12] [14]

Red flags

- Corneal ulcer (bacterial, viral, or fungal)
- Contact lens-related red eye
- Corneal foreign body
- Neonatal conjunctivitis
- Penetrating ocular trauma
- Chemical trauma
- Scleritis
Assessment of red eye

Emergencies

- Anterior uveitis
- Angle-closure glaucoma
Step-by-step diagnostic approach

Current history

When taking the presenting history of red eye, it is important to consider the serious vision-threatening diagnoses along with more common causes. By including key questions and noting down pertinent negative features, the differential diagnosis can be narrowed and a decision can be made on whether referral for further ophthalmological treatment is required or treatment can be given in the primary care setting.

Key questions to consider include:[15]

- When did the condition start?
- Is the condition unilateral or bilateral?
  - A foreign body or trauma is usually unilateral, whereas conjunctivitis may start as unilateral and then become bilateral.
- Was the onset of the symptoms acute or gradual?
  - Acute onset may indicate a corneal foreign body or abrasion or foreign body trauma.

The most important associated symptoms to note in the history are the presence of reduced visual acuity or a deep aching pain within the eye, indicating the presence of a more serious underlying diagnosis, such as angle-closure glaucoma, anterior uveitis, or scleritis.

If the patient reports a foreign body sensation, the possible diagnoses are conjunctivitis, conjunctival/subtarsal foreign body, corneal foreign body, keratitis, and corneal ulcer. If a foreign body is suspected, ask whether the patient has undertaken any recent activity that could have resulted in this and, if so, whether he or she was wearing eye protection. The nature of the activity will also point to potential penetrating injuries: for example, the use of mechanical saws and hammering can produce high-velocity foreign bodies, which have the ability to penetrate the surface of the globe and become intra-ocular.

If the patient wears contact lenses, contact lens-related red eye should be referred for further ophthalmological review, as corneal ulceration must be excluded.
If there is any discharge present, factors that can help to identify the presence of conjunctivitis and the possible underlying aetiology are:[16]

- Watery, purulent, or mucopurulent discharge; for example:
  - A watery discharge is seen in viral conjunctivitis
  - A profuse mucous discharge is seen in chlamydial conjunctivitis
  - A purulent discharge is seen in gonococcal conjunctivitis
- Discharge that is worse in the mornings:
  - May be due to allergy
- Presence of itch:
  - Usually due to allergy
  - Minimal itch may be present in chlamydial conjunctivitis
- History of atopy.

If the patient is photophobic, this can indicate possible underlying anterior uveitis or corneal epithelial disturbance. The systemic associations of photophobia, such as meningitis, should always be considered in an unwell patient.[17]

Past medical and past ophthalmological history

The physician should consider whether the patient has had previous similar episodes or whether there are any underlying systemic associations of conditions known to cause red eye, such as:

- HLA-B27 histocompatibility complex-positive patients
- Reactive arthritis
- Tuberculosis, syphilis
- Lyme disease
- Sarcoidosis
- Behcet's disease
- Pauciarticular juvenile chronic arthritis
- Connective tissue disorders (including rheumatoid arthritis, Sjogren's syndrome, and systemic lupus erythematosus)
- Granulomatosis with polyangiitis (Wegener's)
- Relapsing polychondritis
- Hypertension.

Drug history

The current use of any ophthalmological medications as well as any systemic medications known to precipitate causes of red eye should be noted. These include mydriatics and systemic anticholinergic medications. Patients on anticoagulants may be predisposed to subconjunctival haemorrhage. Persistence of conjunctivitis despite topical antibiotics should prompt evaluation for a different aetiology.
Examination

Examination of the eye in a primary care setting requires the use of a Snellen chart, a light source, fluorescein, and a cotton wool bud to evert the upper lid.[16] A step-wise approach can be used, with consideration of the differential diagnosis from the history.

1. Visual acuity should be checked in all patients, as a reduction may indicate a more serious underlying cause for the red eye.

2. Inspection of the lids and brow should be performed to exclude peri-orbital injury. The position of the lid margins should be checked for the presence of trichiasis, an entropion, or an ectropion. If any discharge can be seen, conjunctivitis should be considered. If the condition is bilateral with purulent discharge, it should be treated as conjunctivitis.

3. On inspection of the ocular surface and subtarsal surface, the pattern of redness, an important feature, should be assessed. Segmental injection may indicate episcleritis or the presence of a foreign body. Ciliary or limbal (junction of the cornea and sclera) injection occurs in anterior uveitis and corneal conditions. Redness that is localised and well demarcated with quiet surrounding conjunctiva is seen in subconjunctival haemorrhage, prompting the patient's blood pressure to be checked. Generalised injection, with engorgement of the deeper scleral vessels and pain on palpation of the globe, indicates the presence of scleritis.[18] The tarsal conjunctiva should be inspected for papillae, seen in allergic conjunctivitis, or follicles, seen in chlamydial conjunctivitis. If there is a history of a foreign body, the upper lid should be everted with a cotton wool bud to exclude a subtarsal position. If the foreign body cannot be found and the activity during the incident may have produced a high-speed foreign body, then further ophthalmological opinion should be sought to exclude an intraocular position. Instilling fluorescein during inspection of the ocular surface can allow the visualisation of foreign bodies, corneal abrasions, and corneal ulcers. If there is fluorescein staining present on the cornea or the cornea appears cloudy (seen in angle-closure glaucoma), referral for further ophthalmological examination is advised. Rose bengal stain can be used in patients in whom dry eye is suspected as the underlying cause.

4. Pupillary reactions. The physician should observe for anisocoria (unequal pupil size), and if this is present should refer for further ophthalmological assessment.[19] Using a pen torch (or equivalent light source), the direct and consensual pupillary responses should be checked. If the pupillary response is abnormal in the presence of red eye, anterior uveitis and angle-closure glaucoma need to be excluded. If the patient is photophobic on examination, further referral is also advised.[20]
Investigations

Swabs for bacterial, viral, and chlamydial culture can be taken in patients with suspected conjunctivitis. Investigation into the underlying systemic causes of red eye should be performed in a specialist clinic after a definite ophthalmological diagnosis has been given. Certain local causes of red eye including ectropion, entropion, corneal ulcer, contact lens-related red eye, corneal abrasion, corneal foreign body, penetrating and chemical trauma, scleritis, and angle-closure glaucoma should be evaluated further by an ophthalmologist.

Computed tomography imaging of the orbits should be performed if a high-velocity penetrating injury is suspected.

If acute glaucoma is suspected, intra-ocular pressure should be measured in the emergency department.
## Differential diagnosis overview

### Common

- Trichiasis
- Entropion
- Ectropion
- Blepharitis
- Dry eye
- Corneal ulcer (bacterial, viral, or fungal)
- Contact lens-related red eye
- Keratitis
- Corneal foreign body
- Corneal abrasion
- Subtarsal conjunctival foreign body
- Allergic conjunctivitis
- Bacterial conjunctivitis
- Viral conjunctivitis
- Non-traumatic subconjunctival haemorrhage

### Uncommon

- Chlamydial conjunctivitis
- Neonatal conjunctivitis
- Penetrating ocular trauma
- Chemical trauma
- Episcleritis
### Uncommon

### Common

#### Bacterial conjunctivitis

**History**
gonococcal aetiology; often initially unilateral, becoming bilateral; eyelid erythema and oedema; vision minimally or unaffected; not itchy

**Exam**
fluorescein stain; normal visual acuity and pupil response

**1st Test**
including Chlamydia: positive
Positive cultures taken from the conjunctivae or discharge can enable treatment to be initiated or changed appropriately.  
[Fig-6]

**Other tests**

#### Viral conjunctivitis

**History**
discomfort, foreign body sensation; watery discharge (not purulent), often profuse; usually initially unilateral, becoming bilateral; associated upper respiratory tract infection symptoms; recent contact history of someone with red eye; vision minimally or unaffected

**Exam**
diffusely injected conjunctiva; tarsal conjunctival follicles; clear cornea initially, possible small patches of sub-epithelial infiltrates developing 2 to 3 weeks after onset; occasionally palpable pre-auricular lymph nodes; no corneal fluorescein stain; normal visual acuity and pupil response

**1st Test**
»conjunctival swabs for micro culture and sensitivity including Chlamydia (to exclude those diagnoses): positive in bacterial or fungal cause
Viral conjunctivitis is usually a clinical diagnosis.  
[Fig-7]

**Other tests**
Conjunctival swabs are performed to exclude bacterial or fungal diagnoses. Positive cultures can enable treatment to be initiated or changed as needed.

#### Non-traumatic subconjunctival haemorrhage

**History**
spontaneous; occasionally history of Valsalva manoeuvre, coughing, sneezing, or heavy lifting;

**Exam**
well-circumscribed area of confluent haemorrhage underneath conjunctiva (if the posterior

**1st Test**
»clinical diagnosis: no initial test
Subconjunctival haemorrhage is seen as a well-

### Episcleritis

**History**

Severity ocular pain and redness (prominent feature); no discharge; reduced visual acuity may be present; past medical history should be reviewed for any known systemic associations.

**Exam**

Deep scleral vessel engorgement and pain on ocular palpation; no fluorescein stain; visual acuity and pupillary reactions may be abnormal depending on the position of the eye.

**1st Test**

- Specialist clinic to evaluate for underlying autoimmune disease.

**Other tests**

- **Rheumatoid factor:** positive in some patients with rheumatoid arthritis, systemic lupus erythematosus.

**Evaluation for causes of episcleritis** should be performed in a specialist clinic to evaluate for underlying autoimmune disease.

- **C-antineutrophil cytoplasmic antibody (c-ANCA):** positive in granulomatosis with polyangiitis (Wegener’s).

**Evaluation for causes of episcleritis** should be performed in a specialist clinic to evaluate for underlying autoimmune disease.

- **Fig-17**

### Scleritis

**History**

Severe ocular pain and redness (prominent feature); no discharge; reduced visual acuity may be present; past medical history should be reviewed for any known systemic associations.

**Exam**

Deep scleral vessel engorgement and pain on ocular palpation; no fluorescein stain; visual acuity and pupillary reactions may be abnormal depending on the position of the eye.

**1st Test**

- **FBC:** result depends on underlying cause.

**Other tests**

- **Evaluation for causes of scleritis** should be performed in a specialist clinic to evaluate for underlying autoimmune disease.

**Fig-17**
